Conclusion

Oral

- the oral is entirely based on the assignments
- we remove some pieces of code from the working solutions and you fill them back in
- the oral gives you the final grade for the course

Expected study effort

- between 10 and 20 **net**^a hours a week
- read every term on the slides and every sample
- if you do not understand it perfectly, either ask a teacher, google, or brainstorm with other students
- every sample of code on the slides you should both **understand** and **try out** on your machine

^aNo, 9gag does not count even if the slides are open on another monitor

Introduction and motivation

- We will use Java and C#
- They are extremely similar in philosophy, syntax, type system, and semantics
- Each one apart is somewhat limited
- Together they cover a huge chunk of theory and practical applications

Conclusion

Java

- Dominantly used in businesses
- Extremely Immense ecosystem of tools and libraries
- Great support on most platforms
- A large community means dozens of libraries for most common tasks

C#

- Dominant in semi-high performance applications (games, simulations)
- Extremely clean and careful design of libraries and advanced language constructs
- Good support on most platform

Conclusion

Java

- Slow to evolve, because of input from developers
- Less clean design with lots of historical corner cases

C#

- Less adopted outside the Microsoft world, though Mono and .Net Core are helping
- Historical bad perception of the whole company polluted language reputation
- No immense collection of competing libraries and build systems

Practicum and assignments

- Just choose whatever you like the most
- Both languages and all supported libraries are accepted
- Moreover, the differences between the two are minimal: learn one, but be aware that you are also learning the other
- We will point the differences out whenever needed

- Most basic Python constructs translate almost directly to Java/C#
- Lines and instructions always end with a semicolon (;)
- Variables are always declared before use, specifying their type.

```
1 x = (10 + 20)

The above Python becomes, in C#:

```
1 int x;  
2 x = (10 + 20);

What have we

From Python
to Java/C#

Conclusion

Java/C# support similar sets of primitive data types

- integers in various sizes: byte, short, int, long, and many others
- floats in various sizes: float and double
- strings: string

These types are richer than Python, because we can specify their size, and thus precision, instead of the one-size-fits-all solution of Python

What have we
learnt so far?

Modern,
object-

programming
languages

From Python
to Java/C#

Conclusion

Each primitive data type has a different range and uses more or less memory

- byte is 1 byte, and it goes from -128 to 127
- short is 2 bytes, and it goes from -32,768 to 32,767
- int is 4 bytes, and it goes from -2^{31} to $2^{31} - 1$
- float is 4 bytes, and it has a very wide range **with non-uniform steps between adjacent values!**...

Some bugs may depend on attempts to write beyond the range or at a higher precision than supported by the type.

Conclusion

Control flow statements

- Java and C# are curly-bracket languages
- This means that any block of code must now appear between curly brackets { and }
- There are no more colons (:) to delimit declarations
- Indentation remains important for the reader^a, but the languages do not care
- Programs in Java/C# tend to be longer in part because of this

^aAnd the student aiming for a passing grade!

Classes

- Java/C# are object-oriented languages
- This means that (almost) everything is an **object**, that is an instance of a **class**
- All Java/C# programs will therefore begin with a class definition

Conclusion

A class in Java/C# looks very much like a Python class, with some minor differences:

- `__init__` is a method with the name of the class itself
- all fields must be declared, like variables, within the body of the class
- `self` is now called `this`

```
1 class Counter:
2     def __init__(self):
3         self.cnt = 0

The above Python becomes, in C#:

```
1 class Counter {
2     private int cnt;
3     public Counter() {
4         this.cnt = 0;
5     }

Visibility

- We can limit visibility of attributes (and methods) in a class in Java/C#;
- This means we can prevent a user of a class from accidentally using something in the wrong way
- Most important attributes are
 - public, means every part of the program can access it
 - private, means it can only be accessed from inside the class
- We assume for the moment that the constructor will always be public

Conclusion

Assuming `x` being an instance of `C`, this would be an invalid program:

```
1  class C {  
2      private int a;  
3      public int b;  
4      public C() {  
5          a = 0;  
6          b = 0;  
7      }  
8  }  
9  ...  
10 Console.WriteLine(x.a)
```

In what sense invalid?

```

In what sense invalid?

The **compiler** will literally refuse to run the program by saying that `a` is private, and thus may not be accessed.

Conclusion

Assuming `x` being an instance of `C`, this would be a valid program, just like in Python:

```
1  class C {  
2      private int a;  
3      public int b;  
4      public C() {  
5          a = 0;  
6          b = 0;  
7      }  
8  }  
9  ...  
10 Console.WriteLine(x.b)
```

This suggests that Python is like Java/C# where all class attributes are automatically declared as public.

From Python to Java/C#

If we want to add methods, we also need to be aware of the type of each of their parameter and of the type they return.

Methods

- Methods can, just like attributes, either `private` or `public`
- `public` methods can be called from anywhere
- `private` methods may only be called from inside the class itself

From Python to Java/C#

Now that we have a class, we can instantiate it and call its methods.

```
1 class Counter:
2     def __init__(self):
3         self.cnt = 0
4     def incr(self,diff):
5         self.cnt = (self.cnt + diff)
6 c = Counter()
7 c.incr(5)
```

The above Python becomes, in C#:

```
1 class Counter {
2     private int cnt;
3     public Counter() {
4         cnt = 0;
5     }
6     public void incr(int diff) {
7         this.cnt = (this.cnt + diff);

Static methods

Surprisingly, both Java and C# miss simple functions like those of Python: this means that they need to be emulated as methods.

Conclusion

Simple Python functions become *static methods* in both Java and C#.

```
1 def f(x):  
2     return (x + 10)
```

The above Python needs to be put inside a class and be marked as *static*, in both Java and C#:

```
1 class MyClass {  
2     public static int f(int x) {  
3         return (x + 10);  
4     }  
5 }

static methods are called without an instance of the class left of the dot, but rather with the name of the class they are declared in

```
1 class MyClass {  
2     public static int f(int x) {  
3         return (x + 10);  
4     }

The exttttMain method

- Java and C# programs do not just begin at the top of a file.
- The program is a class with a special static method, called `main`.
- The arguments to this method are an array of strings, the command line parameters^a.

^aJust ignore, it is mostly not used.
